Optical Shutters

Features

- Mounted and unmounted design options
- Maximum switching speed performance
- Unlimited OEM sizes and shapes
- Fifty percent duty cycle operation
- Portable and lightweight
- No mechanical motion

Applications

- Three-dimensional imaging
- Optical instrumentation
- Telecommunications
- Holography
- Printing

Benefits

- Meets your application-specific requirements
- Silent, vibration-free, low-voltage operation
- Solid state construction
- Affordably priced

Description

An Optical Shutter is a two-state device used to rapidly open and close a light path (from lens to film, for example). Optical Shutters are typically used to control the amount of time that a light-sensitive material is exposed to optical radiation. Figure 1 provides a conceptual illustration of the function of an Optical Shutter.

Boulder Nonlinear Systems (BNS) manufactures and sells liquid crystal based Optical Shutters for applications requiring active timing control of beam transmittance. Key features of our Optical Shutters include high-speed binary operation, high purity linear polarized output, and maximum extinction ratio performance. Since these devices are solid state – undesirable mechanical motion, associated noise, and vibration problems are eliminated.

**MS Series Optical Shutters**

**Maximum switching speed performance**

The MS Series offers a significant performance advantage in Optical Shutter applications demanding the fastest optical response times, typically ranging from 15 – 200 µs. Attractive for their high switching speeds, MS Optical Shutters require a dc-balanced ac drive signal, typically resulting in 50% duty cycle operation. Minimum drive voltage levels are required; as low as ± 5 V ac is sufficient for most applications.

**Device Construction**

Figure 2 below provides a typical Optical Shutter cross section.

MS Series Optical Shutters begin with polished, optically flat windows. After deposition of a transparent conductive coating layer (indium-tin oxide or ITO, typically) these window substrates are then evenly covered with a polymer layer, which is then rubbed or buffed, forming tiny microgrooves in the polymer layer. These microgrooves provide the alignment directionality critical in liquid crystal device production.

The coated and buffed windows are then spaced a few microns apart. The cavity between substrates is now filled with liquid crystal material and sealed.

High extinction linear polarizers are crossed, and then laminated between glass substrates. External glass surfaces are usually coated with a broadband antireflection coating, to maximize transmittance. With this crossed polarizer orientation, MS Series Optical Shutters exhibit full optical transmittance at the negative voltage state. Minimum transmission occurs at the positive voltage level, as specified with your device.

### Company Profile

Boulder Nonlinear Systems, Inc. (BNS) is an innovative technology company specializing in dynamic liquid crystal polarization control solutions for both laser-based and imaging systems. Company strengths in scientific research and development are leveraged into OEM and standard product offerings targeted for astronomy, biomedical, defense, microscopy, optical computing, optical storage, and telecommunications applications.

For additional product and company information, please contact:
